**Abstract:** - Due to the enhanced digital media on the web, information security and privacy protection issue have attracted the eye of information communication. Information hiding has become a subject of sizable importance. Currently each day there's very big drawback of information hacking into the networking space. There is variety of techniques offered within the trade to overcome this drawback. So, information hiding within the encrypted image is one in all the solutions, however the matter is that the original cover can't be losslessly recovered by this system. That's why recently; additional and additional attention is paid to reversible information concealing in encrypted pictures however this technique drawback low hardness. A completely unique technique is planned by reserving for embedding information before encoding of the image takes place with the offered algorithmic rule. Currently the authentic person will hide the information simply on the image to produce authentication. The transmission and exchange of image additionally desires a high security. This is the review paper regarding this reversible information hiding algorithms obtainable. As a result, because of histogram enlargement and bar graph shifting embedded message and also the host image may be recovered dead. The embedding rate is enhanced and PSNR magnitude relation using novel technique.

**KEYWORDS:** *Reversible Data Hiding, Image Encryption, Image Decryption, Histogram Shifting, Data Hiding, Image Recovery, PSNR.*

### **I. INTRODUCTION**

Data hiding within the encrypted pictures by allocating memory before cryptography is used to recover the first cover with none loss & errors. It's primarily utilized in the medical metaphors, military metaphors and law forensics, wherever no distortion of the first image is allowed. In this, the terribly initiative applied is to order the memory area into the image for information embedding. It's useful as a result of it saves the time for making area for information on time. Then the image cryptography is stepped within which the information is embedding. There is range of strategies for the image cryptography like image partition within which image is split into 2 elements. Then part 1st is reversibly embedded into the part second. That's least important bits are embedded 1st partially second [1]. Reversible information hiding Techniques as once information is embedded into the image then the standard of image get disturbed. Therefore it's expected that once the info extraction the image quality ought to be maintained similar to the first image. However that image contains some distortions. With regard of distortion in image, Kalker and Willems established a rate-distortion

copy for RDH, through that they showed the rate-distortion bounds of RDH for while not memory covers and planned a algorithmic code development that, however, doesn't move towards the sure [2]. In this they used the secret writing and decryption. Information hiding may be a technique for embedding info into covers like image, audio, and video files, which might be used for media notation, copyright protection, integrity authentication, covert communication, etc. Most information concealment strategies introduce messages into the duvet media to come up with the marked media by solely modifying the smallest amount important a part of the cover and, thus, ensure sensory activity transparency. The embedding method can sometimes introduce permanent distortion to the cover, that is, the first cover will ne'er be reconstructed from the marked cover. However, in some applications, like medical representational process, military representational process, and law forensics, no degradation of the first cover is allowed. In these cases, we'd like a special reasonably information concealment methodology, that is named as reversible information hiding (RDH) or lossless information hiding, by that the first cover may be lossless restored once the embedded message is extracted. Fig.1 shows easy model of Reversible information hiding (RDH) Message this could be done by choosing an encoding key that is use to encode the initial data once encrypting the data or information hiding secret is used and this information hiding secret is embedded on the encrypted data with the assistance of information hider block and this encrypted information containing embedded data is forward the channel. This will received by image decoding which will decode the received information and by this decode data the initial data is extracted by activity the reverse operation by using an equivalent encode key. Reversible information hiding is mostly supported 2 technologies: distinction growth (DE) [3, 4] and bar graph shifting (HS) [5, 6].

### **Histogram Shifting**

Data hiding technique supported bar graph shifting is used to insert information in cover media by shifting the bar graph of image. This method detects peak and 0 points within the bar graph. By shifting these peak and 0 points information is embedded. It provides high information hiding capability with low distortion. The input image is split into blocks. Shifting of bar graph is finished on every block. Because of that information hiding capability is increased and visual quality is improved further. Embedding image at intervals blocks is a lot of in quantity as compared with embedding at intervals one image. This

method doesn't permit overflow and underflow drawback that's grayscale exceeds on top of 255 or falls below zero. [7].

## II. RELATED WORK

In Ashwind S et al. [8] a Novel method is proposed by reserving room before encryption with a traditional RDH algorithm. It maintains the excellent property that the original image can be lossless recovered after embedded data is extracted while protecting the image content's privacy. An algorithm on Reversible Data Hiding on images and data, not only enhances the data transmission but also data security

In Li. Ming et al. [9], the hidden data is embedded in the encrypted image without data expansion is the principle of designing the holomorphic cryptosystem. In addition, histogram shifting algorithm provides a real reversibility.

X. Zhang et al. [10] proposed a novel scheme for separable reversible data hiding which is made up of image encryption, data embedding and data-extraction/image-recovery phases. The content owner encrypts the original uncompressed image using an encryption key to produce an encrypted image. Then, the data-hider compresses the least significant bits of the encrypted image using a data-hiding key to create a sparse space to accommodate the additional data. At the receiver side, the data embedded in the created space can be easily retrieved from the

encrypted image containing additional data according to the data-hiding key. Since the data embedding only affects the LSB, a decryption with the encryption key can result in an image similar to the original version. When using both of the encryption and data-hiding keys, the embedded additional data can be successfully extracted and the original image can be perfectly recovered by exploiting the spatial correlation in natural image. Following figure shows the three cases at the receiver side.

Che-Wei Lee et al. [11] proposed a lossless data hiding method based on histogram shifting, which employs a scheme of adaptive division of cover images into blocks to yield large data hiding capacities as well as high stego-image qualities. The method is shown to break a bottleneck of data-hiding-rate increasing at the image block size of  $8 \times 8$ , which is found in existing histogram-shifting methods. Four ways of block divisions are designed, and the one which provides the largest data hiding capacity is selected adaptively.

Sruthi et al. [12] this paper presents is a review on RDH reversible data hiding technique. This paper shows that there are difference methods like expansion, interpolation technique, prediction and sorting, histogram modification for data hiding which is now used in encrypted images to improve security. Different RDH algorithms have their own merits and no single approach is optimal and applicable to all cases. This paper is a comprehensive exploration of all the major reversible data hiding approaches and also presents a new method RDH by reserving room before encryption.

In Subhanya R.J et al. [13] presented the paper "Difference Expansion Reversible Image Watermarking Schemes Using Integer Wavelet Transform Based Approach". In this project, they present a new scheme of image watermarking to guard intellectual properties and to secure the content of digital images. It is an effective way to protect the copyright by image watermarking. The work concerns with the watermarking algorithm that embeds image/ text data invisibly into a video based on Integer Wavelet Transform and to minimize the mean square distortion between the original and watermarked image and also to increase Peak signal to noise ratio. Here the message bits (image) are (is) hidden into gray/color images. The size of secret data/image is smaller than cover image. To transfer the secret image/text confidentiality, the secret image/text itself is not hidden, keys are generated for each gray/color component and the IWT is used to hide the keys in the corresponding gray/color component of the cover image. The watermarks are invisible and robust against noise and commonly image processing methods.

Xinpeng et al. [14] the encrypted image holds the hidden data and on decryption the respective image and the hidden data is recovered perfectly by using the encryption key.

Cancellaro et al. [15] the encryption system and water marking provides authentication for the data transmission of a dependent key transformation. The security of the dependent key system is increased.

### **III. EXPECT OUTCOME**

In study in field of reversible digital image information hiding process and secure image information protected in kind of image histogram and information hiding into image exploitation bar graph shifting Techniques. Secure image and authentication image information.

### **IV. CONCLUSION**

A survey on numerous reversible information hiding techniques is performed. Reversible information hiding schemes for encrypted image with a less PSNR computation is analyzed, that consists of image cryptography, information activity and information extraction/ image recovery phases the initial pictures are encrypted by a cryptography strategy. Thus a study regarding a cryptography strategy is performed. Though a data or information hider doesn't know the initial content, he will infix the key information into the encrypted image. Reversible information hiding in encrypted pictures may be a new topic drawing attention as a result of the privacy protective necessities from cloud information management. Previous ways implement RDH in encrypted pictures by vacating area once cryptography, as against that is projected by reserving area before cryptography. Therefore the information hider will take pleasure in the additional area emptied get in previous stage to form data hiding method effort less. This methodology will profit of all ancient RDH techniques for plain pictures and reach wonderful performance while not loss of good secrecy. These novel methodologies are able to do real changeability, separate information extraction and greatly improvement on the standard of marked decrypted pictures.
